Construction regulations with earth in the world

The earth building normative documents in the world

J. Cid, FR Mazarrón, I. Cañas(*)

SUMMARY

The earth has been used as material for

construction for centuries. However, the regulations in this regard are very dispersed, and in most developed countries numerous technical and legal problems arise to carry out a construction with this material. This article studies

the regulatory landscape for constructions with raw earth at an international level, analyzing fifty-five standards and regulations from countries spread over five continents, which represent the state of the art in the standardization of raw earth as a construction material.

It is a referenced study on the current standards and regulations developed by the national standardization bodies or authorities.

corresponding. The regulations and the agencies that issue them are presented, analyzing the structure and content of each one. The most relevant aspects are studied and analyzed, such as stabilization, soil selection, product requirements and existing tests, comparing the different regulations. This work can be very useful for the development of future standards and as a reference for architects and engineers who work with earth.

SUMMARY

For centuries, earth has been used as a construction material. Nevertheless, the normative in this matter is very scattered, and in the most developed coun tries, carrying out a construction with this material implies a variety of technical and legal problems. This article analyzes, in an international level, the normative panorama about constructions with earth. analyzing fifty five standards and regulations of countries all around the five continents; these represent the state of art that normalizes the earth as a construction material. It is a study indexed on the actual procedures and regulations developed by the national organisms of normalization or correspondent authorities. The standards and the organisms that produce them appear, analyzing the structure and the content of each one. We have studied and analyzed

the most relevant aspects, such as stabilization, soil selections, the requisites of the products and the existent test, comparing the diverse normative. The knowledge from this study could be very useful for the development of future standards and as a reference for architects

and engineers that work with earth.

113-110

Key words: norms, construction with earth, blocks of compressed earth, adobe, tapial.

Keywords: standards, earth building, compressed earth blocks, adobe, rammed earth.

1. INTRODUCTION

Earth is increasingly valued as a construction material. Given the growing interest in this ancient material, and in the absence of a legal

framework, many countries try to standardize its use to solve the current problems derived from the absence of regulations that allow the use of construction techniques with raw earth.

There are numerous works that focus on the study of standards and regulations in the field of construction, such as the studies carried out by Soronis (1), Cañas (2), Hooton (3) or Mahlia (4). In the field of application of building with earth, many countries have been working on standardization in recent years, Colombia (2005) and Spain (2008) stand out, with the publication of new standards; Chile, Ecuador, Mexico and Nicaragua, developing future standards; o Peru improving existing documents (5).

This growing activity makes it convenient to analyze the state of the art of standardization for construction with raw earth.

For this, we have carried out a search in a

variety of sources, international standardization organizations, databases, organizations and construction networks with earth, in addition to basing ourselves on lists of regulations already published (2).

Following the classification made by Cañas 2007 (2), the study has focused on the standards issued by the national standardization bodies and the regulations issued by the authorities, according to the European Standard EN 45020: 2007, which in turn adopts ISO/IEC Guide 2:2004 (6). However, although it is not the object of study in this work, it is important to point out the existence of documents that, without having the character of norms or regulations, are important in certain countries, such as the normative documents of Germany or Australia.

2. RULES AND REGULATIONS

In the process of searching and studying international standards and regulations in the framework of construction with raw earth, 55 documents have been located. Table 1 details

the standards or regulations found, where it is indicated: Country, the reference of the Standard or Regulation; the issuing body (ORG); the bibliography reference, which is reflected by the number that appears in the bibliography epigraph of this article (REF); if the document only deals with stabilized earth (EST), and if it contemplates any of the three main techniques on which our study focuses: adobe, mud wall or compressed block (Technique). In Table 2 they are ordered by date of publication of the current regulations of each country.

The set of documents found is very varied. For better handling and understanding, some regulations from the same country have been grouped together. These are the cases of the Brazilian standards for BTC (7-19), the New Zealand ones (32-34), the Peruvian NTP of stabilized adobe (36-38), the collection of the African regional standardization organization ARS 670-683 (39 - 52) and the Tunisian standards (56.57).

From all of them, a set of standards and regulations have been selected that are representative of the international standards for building with raw earth and are valid for detailing the current status (see table 3). In this selection, the Nigerian standard NIS 369 (31) has been discarded due to the difficulty in accessing and obtaining the document; Turkish standards TS 537, TS 2514 and TS 2515 (58-60) for not being written in Spanish, English or French; and the Italian laws (28,29) considering their scarce applicability with a technical-constructive nature.

This selection is structured into fifteen groups of norms and regulations, (counting in the same group all the norms or regulations of a country except in the case of Peru and the US because they have been developed by different entities). All have been issued by national bodies except a New Mexico state standard, the African Regional Body International Standards Group (ARSO), which includes several countries in Africa, and the standard published by the ASTM International Organization. Figure 1 shows the standards and regulations by year of approval in chronological order.

Group 1: Brazil

Brazil has issued thirteen standards (7-19), developed by the Brazilian Association of Technical Standards (ABNT) from 1986 to 1996, on soil-cement and its construction applications in the form of soil-cement blocks and monolithic walls. .

Group 2: Colombia

In 2005, the Colombian standard NTC 5324 (20) was issued, edited by ICONTEC, being a translation of the French experimental standard XP P13-901,2001(24) of AFNOR on BTC.

Group 3-4: USA

The New Mexico regulation (21) is issued by the CID (Construction Industries Division) in 2004, based on two currently repealed codes

Construction regulations with earth in the world

The earth building normative documents in the world

Recently, the international organization "American Society for Testing and Materials" has developed the technical standard ASTM E2392 M-10 (22) approved in January 2010 and published in March of that year.

Group 5: Spain At

the end of 2008, the first Spanish standard (23) for construction on earth was developed, and the first current non-experimental European standard for compressed earth blocks, issued by the AEN/ CTN 41 SC 10 "Building cation with raw earth" from AENOR.

Group 6: France

The XP P13-901:2001 (24) experimental standard is a provisional document accessible to the public, developed by the national organization AFNOR in order to obtain the necessary experience in its application, on which to base a future standard.

Group 7: India

The regulatory body in India since 1987 is the BIS (Bureau of Indian Standards) whose predecessor was the ISI (Indian Standards Institution) which published the revised IS 2110 (25) standards in May 2007, the IS 1725 standard (26) and the IS 13827 standard (27).

Group 8: Kenya

KS 02-1070 (30) issued by the KBS (Ken ya Bureau of Standards) is a revision of the 1993 standard.

Group 9: New Zealand

In 1996, the three standards issued by the national organization SNZ (New Zealand Standards) (32-34)

Group 10-11: Peru

The Peruvian standard NTE E 080 (35) of 2000 comes from a previous version of 1977 of the ININVI (National Institute for Housing Research and Standardization) which was ab

absorbed by the public body SENCICO (National Service for Standardization, Training and Research for the Construction Industry). Currently the Peruvian standard is undergoing a second revision and expansion. The NTP standards (36-38), issued by the Peruvian Standardization System INDECOPI.

Group 12: Regional Africa In

1998, 14 standards on BTC were issued (39-52) by the African Regional Organization for Standardization (ARSO) published in a technological series of the CDI/CRATerre (60).

Group 13: Sri Lanka The Sri Lanka Standards Institute (SLSI) develops

at the end of 2009 three standards on stabilized compressed earth blocks (53-55).

Group 14: Tunisia

Two NT standards (56,57) published in 1996 by the Tunisian standardization body, INNORPI.

Group 15: Zimbabwe

The Zimbabwe standard (61) was issued in 2001 by the National Standards Agency (SAZ) and is based on a publication by Keable 1996 (62).

3. ANALYSIS OF THE STRUCTURE AND CONTENT OF THE REGULATION INTERNATIONAL

A large part of the documents analyzed (79%) focus their content on the study of a single construction technique, be it adobe, BTC or mud. The remaining papers examine various techniques. In this way, the SAZS 724 (61) and IS 2110 (25) standards are exclusive for tapial. Containing provisions only for adobe is the Peruvian NTE E 080 (35) and, for adobe is-

stabilized with asphalt, NTP 331.201, NTP 331.202 and NTP 331.203 (36-38). Regulating only the compressed earth block are the French XP P13-901 (24), the Colombian NTC 5324 (20), the Kenvan KS 02-1070 (30), the African regional collection ARS 670 to ARS 683. (39-52), the NT 21.33 and NT 21.35 (56.57) and the Spanish standard UNE 41410 (23).

The Brazilian one is exclusively made of compressed earth blocks, except for the NBR 13553 (19) standard, which includes a monolithic wallhd most complete document is the New Indian standards IS 2110 and IS 1725 (25,26) regulate rammed earth (soil-cement walls) and BTC respectively. NMAC 14.7.4 (21) deals primarily with the three main techniques, although it also includes lumps and clods. The most complete of the thirteen is the New Zealand one, a collection made up of NZS 4297, NZS 4298, NZS 4299 (32-

34), which includes adobe, compressed earth block and mud wall, as well as poured earth. For information only, it also offers recommendations for cob and adobe in-situ. As can be seen, only two deal with the three main techniques at the same time, NMAC 14.7.4 (21) and the NZS (32-34). It is noteworthy that of the fifteen group of standards, eleven dedicate part or all of their norm to the compressed ground block.

In terms of content, we can say that the largest Zealand trio (32-34), since it ranges from material and construction requirements to issues of structural design and durability of earthen buildings, and both for adobe as for compressed earth block or tapial. The content of this group of standards is somewhat smaller in terms of unit manufacturing, topic

Table 3

Selected rules and regulations and content

which is found in the Brazilians (9-10) and the ARS 680 (49) for the compressed earth block. Construction and performance provisions appear in detail only in New Mexico NMAC 14.7.4 (21), Zimbabwe SAZS 724 (61), Peru NTE E 0.80 (35), New York NZS 4298 (33) Ze land and Africa ARS 682 (51).

The ones that dedicate more content to structural design are again the New Zealanders (32,33), using limit state design principles in their formulation.

Limitations of slenderness of walls and indications on their bracing are indicated in the New Mexico regulation, NMAC 14.7.4 (21); in Zimbabwe, SAZS 724 (61) and in Peru's NTE E 0.80 (35). What is found in all of them are requirements that must be demanded of the products, through minimum results that must be obtained from a series of tests.

This series of tests in all cases are explained in the standards themselves or referenced to other documents that contain their procedures. Only in the case of NMAC 14.7.4 (21) no reference is found.

All the standards basically consider the use of earthen walls as resistant walls, which could also be used as non-resistant. SW

Unfortunately, the Brazilian standards (11-13,19) place limitations on the use of hollow blocks and monolithic walls without structural function.

Regarding the field of application of these earth techniques, some standards limit the height for load-bearing walls to a maximum of two floors (21) or not exceeding 6.5 m in height from the top of the foundation to the top. of the earthen wall (30). On some occasions, categories of buildings are established as in the NZS standards (32-34), normal category one or two heights whose requirement are some minimum properties of use, surface, height of walls, thicknesses, load, etc. and one.

And a special category that exceeds all the characteristics of the normal category

Regarding areas susceptible to seismicity, the Peruvian standard NTE E 0.80 (35) limits the number of heights, also finding some indications for seismic-resistant design in New Zealand (32-34).

4. RELEVANT ASPECTS OF THE REGULATORY

4.1. Stabilization

In the set of selected standards, it is recommended to add some stabilizing agent (cement, lime...) to improve the characteristics.

mechanical characteristics, durability and stability of the soil, although it is not always essential, since many soils can achieve satisfactory behavior without the need for any stabilizer. The most common stabilizers are cement (21,35,39,61), non-hydraulic and hydrated lime (33,61), or asphalt emulsions for adobe (35).

Some of the standards have exclusively stabilized soil as their object of standardization, in the case of Brazilian standards (7-19), Colombian standards (20), India (26), Kenya (30) or the three Sri Lankan standards for blocks. compressed earth; for adobe the NTP standards of Peru (36-38) and for tapial the Brazilian standard (19) together with the IS 2110 standard (25).

Another approach regarding the use of stabilizers is to set a stabilizer content limit, as is the case of the New Zealand standards (32-34) and the Spanish standard (23). In the case of the Spanish standard, the total content of stabilizers (cement, lime, plaster and others) must be less than or equal to 15% of the dry mass of the block. Except for the US standard (21) which establishes exceeding a water absorption value in the case of adobe, and for mud containing a minimum of 6% by weight of Portland cement, passing the wet compressive strength tests, no another document defines stabilized earth.

4.2. soil selection

In all the standards there are references to the selection of soils, even though the approaches in each of the documents are different and sometimes even scarce (26,30). The most usual are recommendations of results based on certain tests that in many cases are imprecise, not quantifiable or based on preliminary tests.

The most cited group of properties are texture and plasticity (23,24,35,39,40,61) although there are also indications on organic content and salt content, especially if that soil is going to be stabilized. Plasticity and texture diagrams are frequent in the French (24), Colombian (20) or Spanish (23) standards, while in the Brazilian standards (7-19) liquid limit values (ÿ45%) are recommended. and plastic index (ÿ18%) or the values of the different fractions of the soil in other standards such as Peru (35) or Zimba bue (61). Other properties related to the chemical composition of the soil or pH are nonexistent. Another approach is to value the soil according to the construction product that will constitute the walls (21,32-34). This is done because there is no direct relationship between the behavior of the product and the characteristics of the soil used. It is verified through the built elements indicating tests to be carried out and results required according to the technique used (32-34) or by checking the blocks directly (21).

4.3. Product requirements

Next, we will deal with the aspect related to the required properties for the adobe and BTC pieces and also for the case of the wall in which the resulting product of the construction is the wall itself.

The specifications refer to the classification of products, dimensional, geometric, appearance, physical-chemical or mechanical-hygrometric physical characteristics through required (36) or recommended values. These product standards that specify the requirements that must be met to establish its suitability for use are very common in the land regulatory framework (7,11,12,19, 20, 23, 24, 26, 30, 33, 35, 56,57, 61).

In the standards, the required or recommended values are obtained through tests, whose procedure is specified therein, becoming test standards.

This is so because they are not previously standardized or assume variations of the existing ones. These are the cases NBR 8492 (8), NMAC 14.7.4 (21), XP P13-901 (24), IS 1725 (26), KS 02-1070 (30) NZS 4298 (33) or NTP 331.202 (37).

The standards analyzed referring to BTC are found with a broader classification, greater

geometric or appearance characteristics than those referring to adobe pieces. A very usual classification for the types of BTC is according to mechanical restrictions (26), based on the comprehension values, in the case of the Colombian (20), Spanish (23) or ARSO standards (39-52).).

They are usually solid blocks but cracks and perforations are allowed (7-19,39-52), there being limitations to these perforations (33) or being a necessary condition (26).

The reception of compressed blocks and adobe, including the applicable requirements, the sampling to be carried out and the acceptability conditions are included in NTP 331.203, (38), XP P13-901 (24), IS 1975 (26) and ARS 680 (39). Also in the case of the Spanish standard (23) it is required to guarantee all the aforementioned pre-registrations, carrying out the corresponding verifications according to the standard.

4.4. essays

Much of the information collected in standards or building regulations with earth refers to test procedures.

There are publications referring exclusively to trials (8, 13,37,39-52); Other standards introduce tests in annexes, such as IS 1725 (26), KS 02-1070 (30), NZS 4298 (33), SAZS 724 (61); while other documents accompany it to product standards, in the case of the Peruvian (35), French (24) and Spanish (23) standards.

The regulations for building with earth are quite autonomous and test procedures typical of construction techniques with earth are often described, such as erosion tests (33-61). There are also many references to national standards from other fields of knowledge, especially with

regard to soil preparation and classification. Among these references, texture and plasticity stand out, as in the Brazilian standards (7-19),

SAZS 724 (61), NZS 4298 (33), XP P13-901 (24), and the Spanish standard (23); determination of the organic matter content (23,30) or the determination of the optimum moisture content of a soil. For the absorption of water in BTC, many national standards referring to brick are cited (23,24,26).

Some of the most cited tests in the raw earth regulations are erodibility, wetting/drying

cycles and compressive strength. The water fall or pressure spray tests are quite homogeneous in any of the versions carried out (23,26,33,61), while the wetting and drying cycle test procedures are very different in terms of cycles or drying times.

Compression resistance tests are considered indicators of the quality of earth elements, but

very few comparable proposals are found. If we focus on the comprehension test of the BTC pieces, we find two alternatives: test the split and stacked block, in the case of Brazilian standards (7-19) and French standards (24); or rehearse the piece as complete as in the case of the Spanish standard (23), since with the presence of the mortar a new parameter is added in addition to the one of the piece.

There are also tests related to shear stress by diagonal compression (35) or tensile strength tests with modulus of rupture or tensile strength by flexion of individual elements (21, 30, 32-35).

5. CONCLUSIONS

At present, standards with specific purposes are avoided: specifications, manufacturing processes or test methods, tending towards a joint publication for various purposes, as shown in the Spanish or French standard. Most standards are product standards, extending their field of application to test procedures.

In most cases, these types of documents refer to one or two techniques. Standards and regulations that cover earthen construction in its entirety are rarely used.

Of the standards analyzed, those referring to compressed earth blocks stand out, for which there is an abundance of regulations, especially with regard to the specification of the block, geometric, dimensional, appearance, physicalchemical characteristics, etc.

The New Zealand set of standards presents a model comparable to the current approach given to other construction materials, characterized by the good definition of the subject techniques, by the abundant development of all phases of the process for the three techniques and for the detailed description of the proposed test procedures.

It is necessary to standardize the tests applied to constructions with earth, both for pieces and for monolithic walls, in order to carry out an adequate comparative analysis between the different existing construction techniques.

The Asturian hydrographic path of Villaviciosa has been executed with ArteviaTM Arena, a special mortar with which pavements with an aesthetic similar to those known as sand paths are achieved, but with much higher resistance.

The fact that the rain does not make it soft, that it does not generate dust and that infinite creations can be created due to the possibility of coloring the mortar mass, make it the ideal flooring compared to other solutions with similar characteristics. www.lafarge.com.es www.artevia-es.com
